# What is NGI Goal 2.1?

- A “leading edge but stable” infrastructure for providing end-to-end high performance and advanced services (referred to as NGI/I2 class) for the purpose of Goal 3 applications development
- Wide area backbone networks (referred to as “JETnets”) involved in this infrastructure:

(DREN)

# Joint Engineering Team

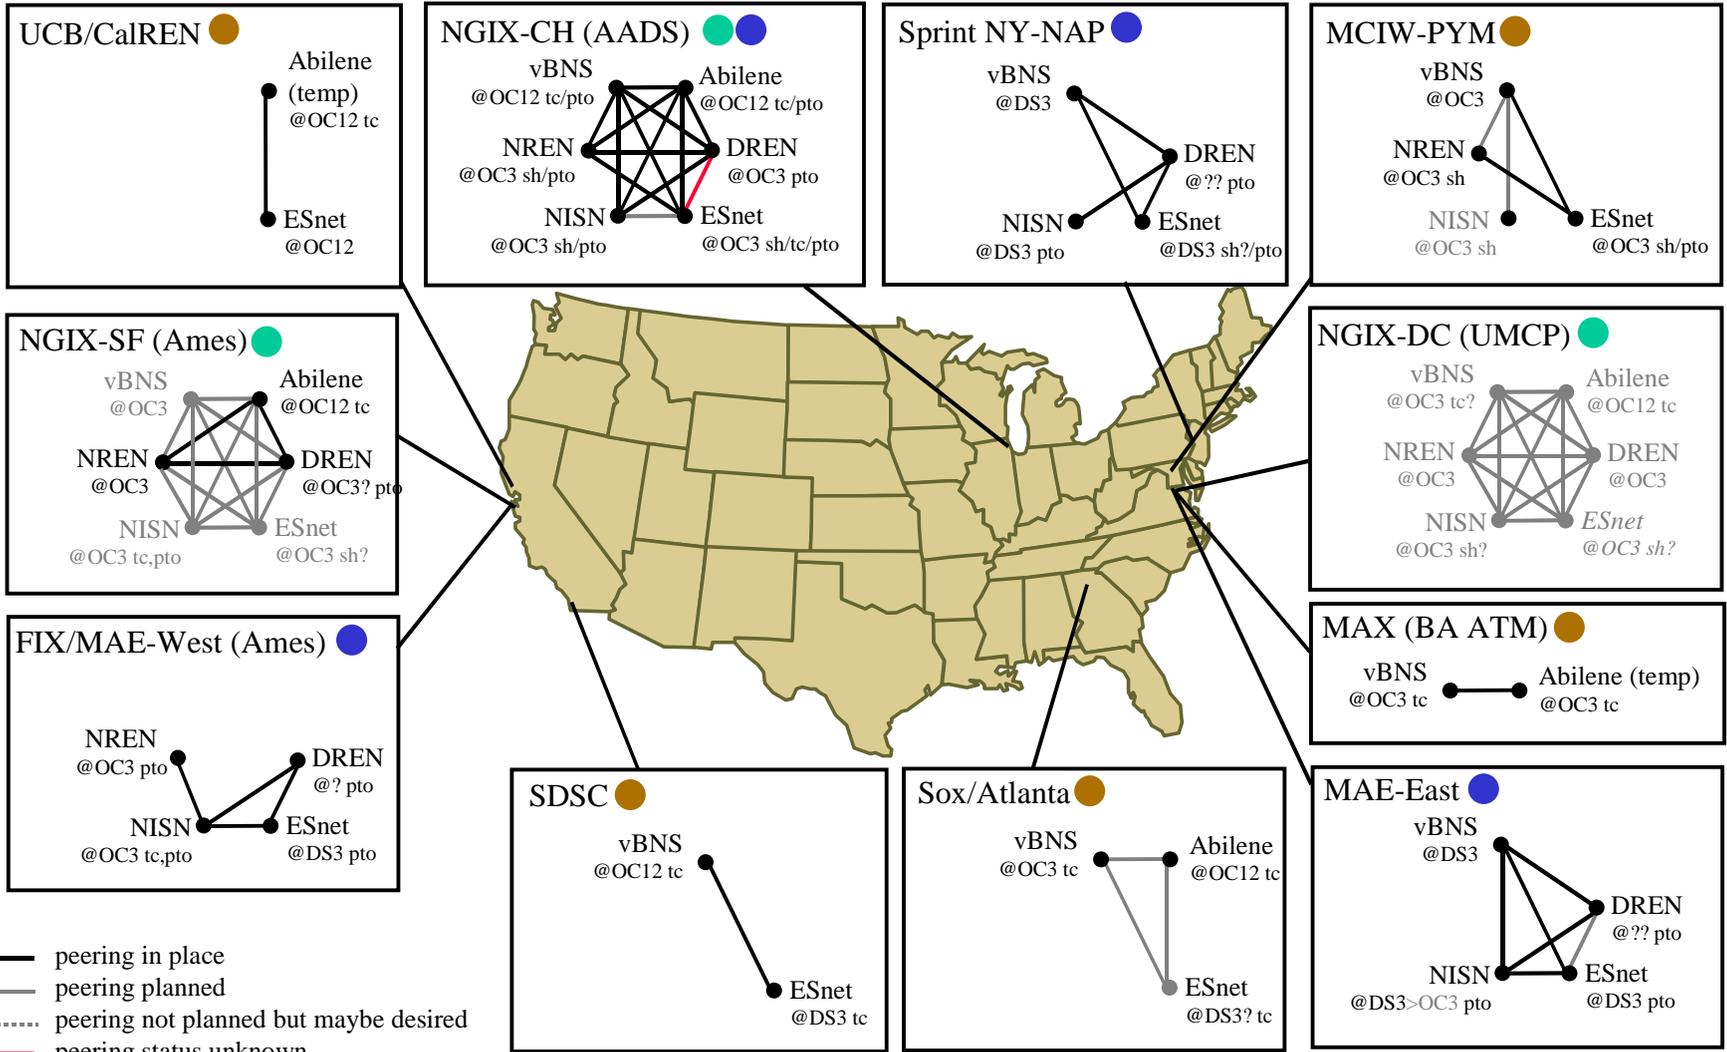

- A forum of NGI, Internet2 and other federal networks/agencies mainly for technical exchange and coordination
- Reports to LSN
- Focused on interconnection and peering of JETnets in support of end-to-end services
- Facilitates joint (inter-agency, states, I2) efforts for special connections like Alaska and Hawaii
- Joint meetings with Gigapop operators
- Very limited campus nets participation

# JETnets NGI Funding and Service Types

<i>Network</i>	<i>NGI Program Funding</i>	<i>NGI/I2 Class Service</i>	<i>Commodity Internet Service</i>
<b>Abilene</b>	Yes	Yes	No
<b>DREN</b>	No	Yes	Yes
<b>ESnet</b>	Yes	Yes	Yes
<b>NISN</b>	No	Limited	Yes
<b>NREN</b>	Yes	Yes	No
<b>vBNS</b>	Yes	Yes	No

NSF funds vBNS (directly and indirectly)  
and Abilene (indirectly)

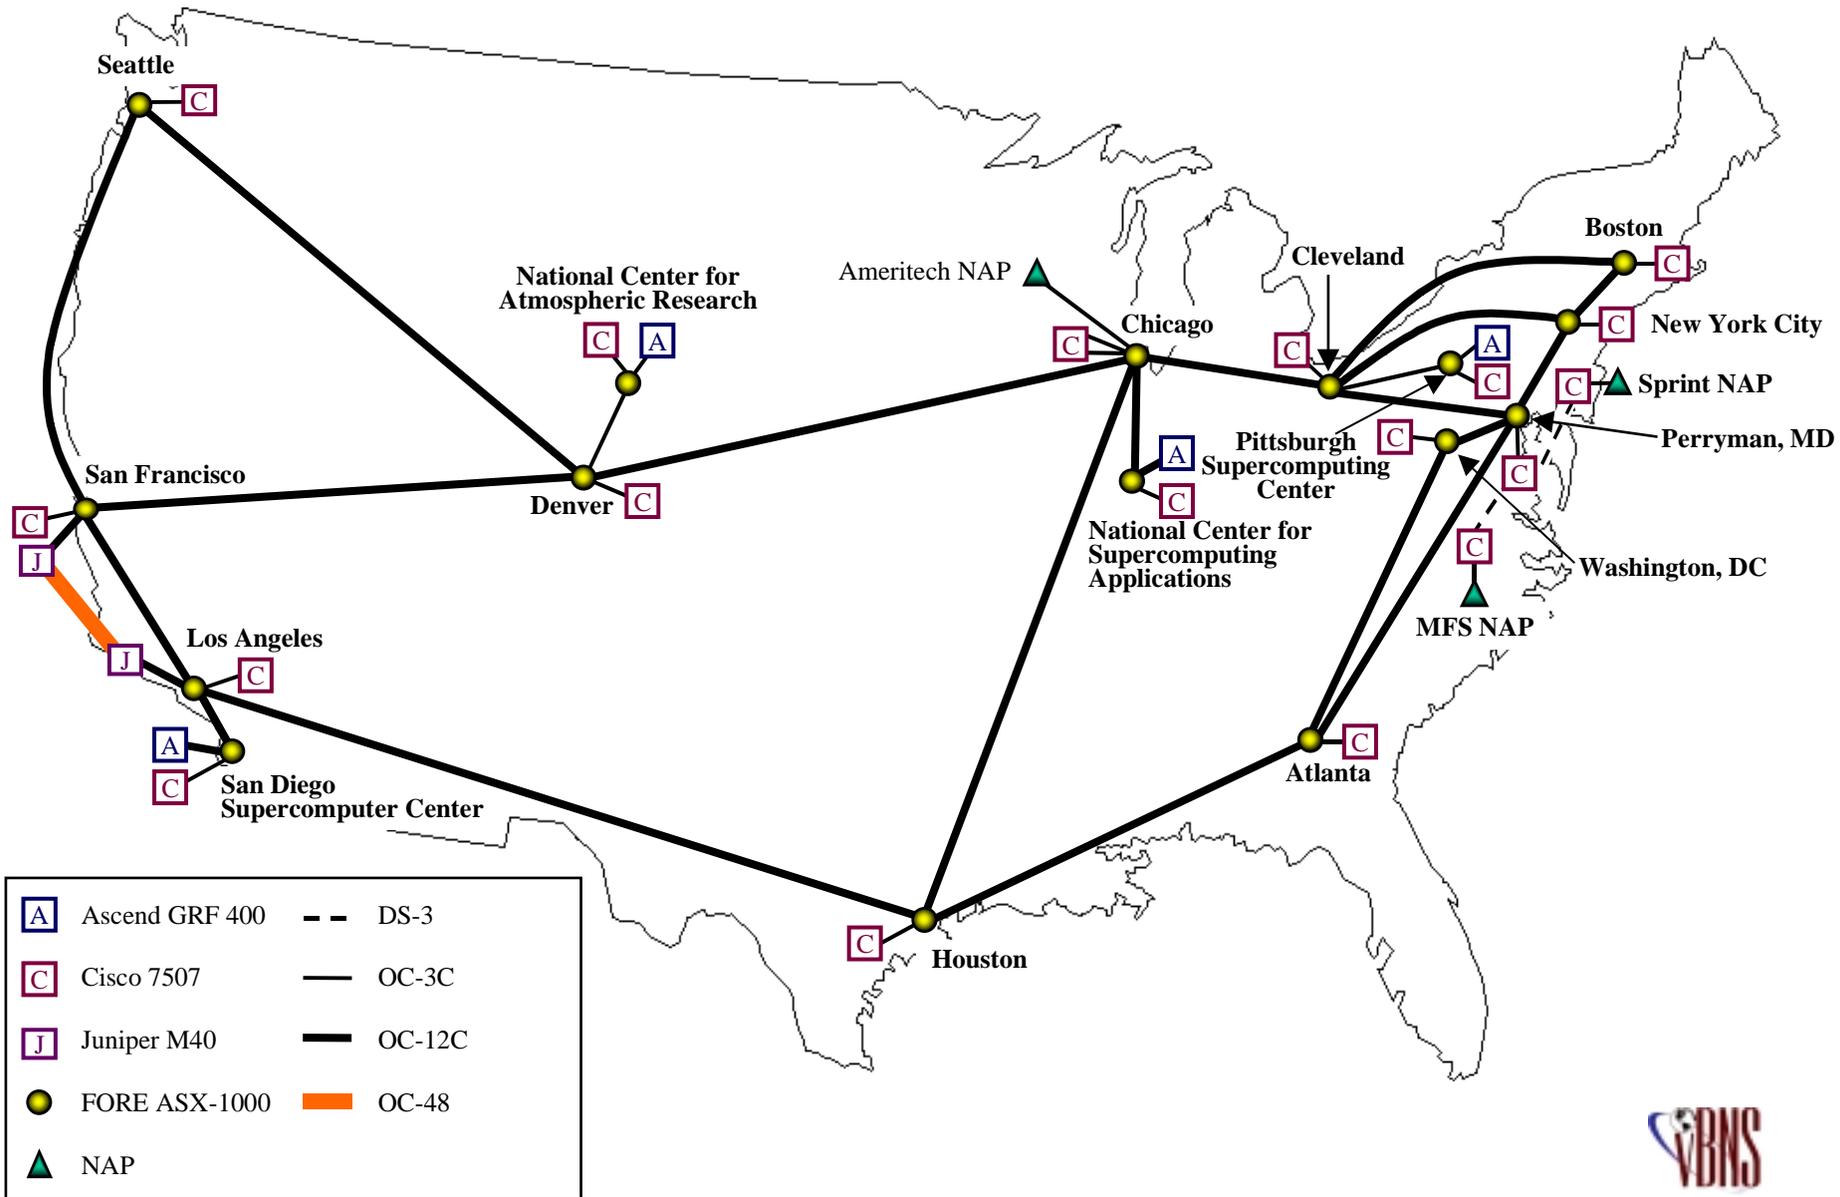

# JETnets Interconnections and Peering

sh: SHared circuit to the exchange point  
 tc: circuit also serving as Tail Circuit for some customers  
 pto: Peering Traffic with Others (non-JETnets) goes on the same circuit  
 temp: Temporary peering until a nearby NGIX is established

JETnet: connected to the exchange point  
 JETnet: plan to connect to the exchange point  
 JETnet: no current plan to connect but maybe desired

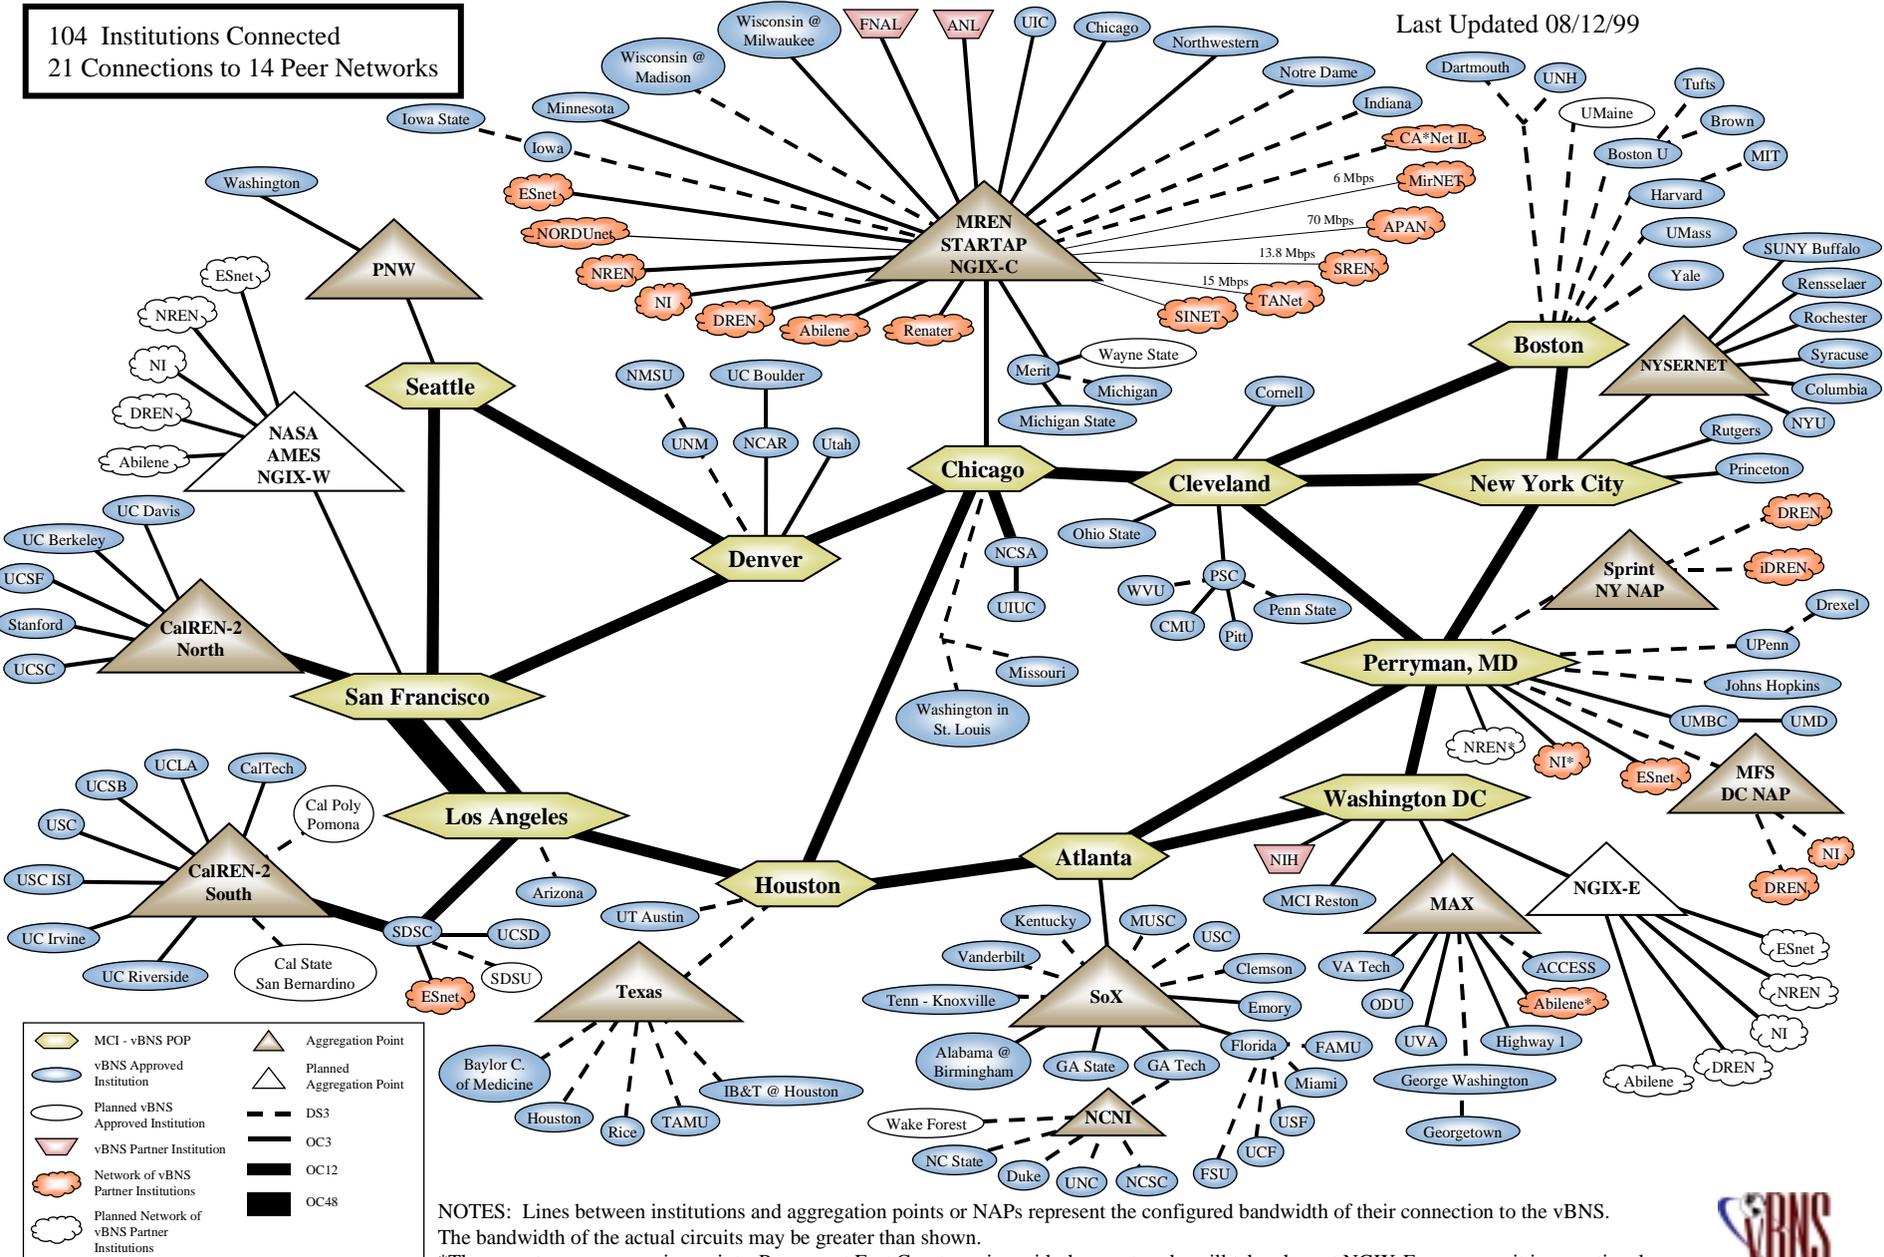

# vBNS Network

# vBNS Connected Sites

Last Updated 08/12/99

104 Institutions Connected  
21 Connections to 14 Peer Networks

NOTES: Lines between institutions and aggregation points or NAPs represent the configured bandwidth of their connection to the vBNS. The bandwidth of the actual circuits may be greater than shown.  
\*These are temporary peering points. Permanent East Coast peering with these networks will take place at NGIX-E as soon as it is operational.

# Advanced Services

- IP multicast: all JETnets (except NISN) have native multicast running in production mode using the PIM-SM, MBGP and MSDP protocols -- 1999 is the year native multicast became real in the backbones (still not on many campuses)
- IP QoS: Abilene, ESnet, NREN and vBNS are active members of the QBone project (inter-domain diffserv); vBNS has offered “reserved b/w” service using RSVP/ATM
- IPv6: all JETnets are part of the 6Bone project and vBNS is testing a native IPv6 service (separate routers)

# Measurement Activities

- Passive measurements: Coral/OCXmon -- totally noninvasive, detailed characteristics of individual flows
- Active measurements: AMP, Surveyor -- including throughput, topology, RTT, one-way delay, delay variation, packet loss
- BGP/SNMP data analysis
- Analysis and visualization tools development
- *Key experts: Hans-Werner Braun (SDSC/NLANR), Kim Claffy (SDSC/CAIDA), Matt Mathis (PSC/NLANR), Kevin Thompson (MCIW/vBNS) and Matt Zekauskas (Advanced/I2 Measurements WG Chair)*

# Performance Expectation and Issues

- For OC3 or higher connected sites with 100Mbps switched campus nets and fine tuned end systems (and no firewall in the path) you can expect 80 Mbps end-to-end (memory to memory)
- This is not the TYPICAL case
- Most performance bottlenecks are in the end systems: lack of path MTU discovery, TCP implementation, multiple memory copying and buffer management; there are also problems in local networks (under-power routers)
- NGI program first phase mostly focused on wide area nets, now we are focusing on local nets and end systems

# Plans for Performance Improvement

- Had two NLANR workshops and special meeting of JET with I2 measurements WG
- Identifying those end systems/applications that have sink/source of large volume traffic; contacting the owners to understand their application and systems and help them with better tuning
- Providing fined tuned laptops for measuring end-to-end performance from particular subnet to help local net operators to find network problems
- Building patches for Linux (possibly getting them into Red Hat release) as a way to encourage other OS vendors to do the same thing
- Labeling sites and end-systems within each site which are capable of 100x performance; eventually making it typical

# vBNS 5 minute samples of high bandwidth flows
